

Installation

Deconik microphone isolator has provided a high-density, portable and easy-to-assemble version of the panel called flexi screen plus. The characteristics of this acoustic panel include the high cohesion of the polyurethane foam that helps to maximize absorption efficiency. This panel surrounds the microphone and produces a clear sound in low and middle frequencies. This panel has a dual function. The inner surface absorbs the frequency and bass of the singer's voice, while the outer surface of the panel absorbs scattered reflections. It performs in the environment of the room. The structure of the acoustic foam has the desired density and thickness. With the design of the holes, it has provided a common mechanism to strengthen the absorption effect and control the reflections. The difference between this model and the flexi screen lite microphone isolator is in the dimensions, which are for small places and the constant need for a microphone isolator, and there is no need to move it around.
